Block 12 — Diode Applications

Learning objectives

After this 90-minute block, you can

- design a simple LED circuit with a series resistor.
- explain why LEDs and signal diodes need current limitation.
- use Z-diodes for simple voltage limitation and voltage stabilization.
- explain how a freewheeling diode protects a switching transistor or contact.
- explain diode clamp circuits for sensitive microcontroller inputs.
- distinguish half-wave, center-tap, and bridge rectifier circuits.
- calculate the ideal average value $\langle U_{\text{di}} \rangle$ of rectified sinusoidal voltages.
- explain ripple voltage and ripple frequency.
- estimate a smoothing capacitor for a simple diode rectifier power supply.

90-minute plan

- **Warm-up (10 min):**
 - What happens if an LED is connected directly to $\langle 24 \text{ V} \rangle$?
 - Recall from [Block 11](#): diode polarity, forward voltage, reverse blocking.
 - Recall from [switching transients](#): inductor current cannot jump.
- **Core concepts (55 min):**
 - LED operation with a series resistor.
 - Z-diode voltage limitation and stabilization.
 - Freewheeling diode for inductive loads.
 - Clamp diodes for sensitive inputs.
 - Diode rectifiers: M1, M2, B2.
 - Capacitor smoothing and ripple.
- **Practice (20 min):**
 - Calculate an LED series resistor.
 - Check Z-diode current limits.
 - Estimate short switching overvoltages in an inductive load.
 - Calculate average rectifier voltages and smoothing capacitors.
- **Wrap-up (5 min):**
 - Which diode application belongs to which engineering problem?
 - Preview: bipolar transistors as controlled switches and amplifiers.

Conceptual overview

- A diode is useful because it is **nonlinear**: it behaves differently for the two voltage polarities.
- In applications, a diode often has one of four jobs:

- **conduct only one half-wave**: rectifier,
- **limit a voltage**: Z-diode or clamp diode,
- **provide a safe current path**: freewheeling diode,
- **emit light**: LED.
- A diode does not magically limit its own current. The circuit around it must do that.
- Real diodes cause voltage drops and losses:

$$P_{\text{D}} = U_{\text{D}} I_{\text{D}}$$

- In mechatronics, diode circuits appear in power supplies, relay drivers, sensor inputs, motor-driver protection, status LEDs, and emergency signal paths.

Scope of this block

This block uses the diode models from [Block 11](#) and applies them to practical circuits.

The focus is on **basic engineering estimates**, not yet on detailed datasheet design.

Core content

LED with series resistor

An LED is operated in forward direction. It converts part of the electrical energy into light.

Start drawing by
clicking here

Fig. ##: LED with current-limiting series resistor.

For a supply voltage (U_{E}) , an LED forward voltage (U_{F}) , and a desired LED current (I_{F}) , the series resistor is

$$\boxed{R_{\text{V}} = \frac{U_{\text{E}} - U_{\text{F}}}{I_{\text{F}}}}$$

The resistor power is

$$P_{\text{R}} = (U_{\text{E}} - U_{\text{F}}) I_{\text{F}} = R_{\text{V}} I_{\text{F}}^2$$

The LED power is approximately

$$P_{\text{LED}} = U_{\text{F}} I_{\text{F}}$$

Do not connect an LED directly to an ideal voltage source. The current must be limited, usually with a resistor or a current source.

<tabcaption tab_led_values|Typical LED values for first estimates>

LED color	Typical forward voltage (U_{F})	Typical current
infrared	$\approx 1.3 \text{ V}$	$\approx 20 \text{ mA}$
red	$\approx 1.6 \text{ V}$	$\approx 20 \text{ mA}$
yellow	$\approx 1.7 \text{ V}$	$\approx 20 \text{ mA}$
green	$\approx 1.8 \text{ V}$	$\approx 20 \text{ mA}$
blue / white	$\approx 3.0 \text{ V} \dots 3.3 \text{ V}$	$\approx 20 \text{ mA}$

Engineering example

A robot controller often uses a (24 V) supply, but a status LED may need only (10 mA) at about (2 V) . Most of the voltage must therefore drop across the resistor, not across the LED.

LED operation with AC voltage

LEDs tolerate only small reverse voltages. Therefore, operation directly at AC voltage needs protection.

Fig. ##: LED operation with AC voltage and reverse-voltage protection.

Start drawing by
clicking here

A second diode can be placed antiparallel to the LED. Then, during the reverse half-wave, the normal diode conducts and limits the reverse voltage across the LED.

For low-frequency indicator circuits, a visible flicker may occur if only one half-wave is used. For higher quality indicators, rectification or dedicated LED drivers are used.

Z-diode voltage limitation and stabilization

A Z-diode is operated in reverse breakdown. In its working range, the voltage is approximately constant:

$$u_{\text{Z}} \approx U_{\text{Z}}$$

Start drawing by
clicking here

Fig. ##: Simple Z-diode voltage stabilizer with load resistor.

The input current through the series resistor is

$$I_{\text{V}} = \frac{U_{\text{E}} - U_{\text{Z}}}{R_{\text{V}}}$$

The load current is

$$I_{\text{L}} = \frac{U_{\text{Z}}}{R_{\text{L}}}$$

The Z-diode current is

$$I_{\text{Z}} = I_{\text{V}} - I_{\text{L}}$$

and must stay in the allowed operating range:

$$I_{\text{Z,min}} \leq I_{\text{Z}} \leq I_{\text{Z,max}}$$

The power limit is

$$P_{\text{Z}} = U_{\text{Z}} I_{\text{Z}} \leq P_{\text{tot}}$$

Color scheme for the Z-diode stabilizer

$$\begin{aligned} I_{\text{V}} &= \frac{U_{\text{E}} - U_{\text{Z}}}{R_{\text{V}}} && \text{current supplied through the series resistor,} \\ I_{\text{L}} &= \frac{U_{\text{Z}}}{R_{\text{L}}} && \text{useful load current,} \\ I_{\text{Z}} &= I_{\text{V}} - I_{\text{L}} && \text{remaining current through the Z-diode.} \end{aligned}$$

The Z-diode can stabilize the voltage only if I_{Z} remains inside the allowed range.

A Z-diode stabilizer is simple, but not efficient for large load currents. It is useful for voltage limitation, small reference voltages, and robust simple circuits.

Freewheeling diode for inductive loads

Inductors resist a sudden change of current:

$$u_{\text{L}} = L \frac{di_{\text{L}}}{dt}$$

If a relay coil, solenoid, or small motor is switched off, the current tries to continue flowing. Without a safe current path, the voltage can become very large.

Fig. ##: Switching an inductive load without freewheeling diode: dangerous overvoltage can

Fig. ##: Switching an inductive load with freewheeling diode: the current has a safe path.

Start drawing by
clicking here

Start drawing by
clicking here

occur.

When the switch is opened, the freewheeling diode becomes forward-biased. The inductor current circulates through the diode and the coil.

Physical interpretation

The coil is like a flywheel for current.

- A mechanical flywheel cannot stop instantly.
- An inductor current cannot stop instantly.
- The freewheeling diode gives the current a safe path while the stored magnetic energy is dissipated.

The magnetic energy stored in the inductance is

$$W_L = \frac{1}{2}LI_0^2$$

With a freewheeling diode, the switch voltage is limited to a safe value. The disadvantage is that the current decays more slowly, so a relay or solenoid may release more slowly.

For fast turn-off, additional components such as a Z-diode, TVS diode, or resistor-diode network can be used. The basic principle remains the same: provide a controlled path for the inductive current.

Clamp diodes for sensitive inputs

Microcontroller and sensor inputs tolerate only a limited voltage range. Clamp diodes can conduct disturbances away from the sensitive input.

Fig. ##: Clamp diodes protecting a sensitive input against overvoltage and undervoltage.

Start drawing by
clicking here

For a $(5 \sim \text{V})$ input, the input node is often clamped approximately to

$$\begin{aligned} & -0.7 \sim \text{V} \lesssim u_{\text{in}} \lesssim 5.7 \sim \text{V}. \end{aligned}$$

The resistor (R_{V}) limits the clamp current:

$$\begin{aligned} & I_{\text{clamp}} \approx \frac{U_{\text{disturb}} - U_{\text{clamp}}}{R_{\text{V}}}. \end{aligned}$$

Clamp diodes are not a substitute for proper EMC design. For external connectors, use suitable protection components and check the datasheets.

Mechatronics example

A sensor cable near a motor cable can pick up short disturbance pulses. Clamp diodes can prevent the input voltage from exceeding the allowed range, while the series resistor limits the injected current.

Half-wave rectifier M1

A rectifier converts an AC voltage into a unidirectional voltage.

Fig. ##: Half-wave rectifier M1 with ideal diode and resistive load.

Start drawing by
clicking here

Assumptions for the basic formulas:

- sinusoidal input voltage,
- RMS value (U_{sim}) ,
- ohmic load,
- ideal diode.

For a half-wave rectifier:

$$U_{\text{di}} = \frac{\sqrt{2}}{\pi} U_{\text{sim}}$$

The ripple frequency is

$$f_{\sigma} = f$$

The ripple factor for the ideal M1 circuit is

$$w_U = \frac{U_{\sigma}}{U_{\text{di}}} \approx 1.21$$

The half-wave rectifier is simple, but it uses only one half-wave. Therefore the ripple is large and the transformer is used poorly.

Center-tap rectifier M2 and bridge rectifier B2

A full-wave rectifier uses both half-waves.

Fig. ##: Center-tap rectifier M2.

Start drawing by
clicking here

Fig. ##: Bridge rectifier B2.

Start drawing by
clicking here

For the center-tap rectifier M2:

$$U_{\text{di}} = \frac{2\sqrt{2}}{\pi} U_{1\text{N}} = \frac{\sqrt{2}}{\pi} U_{\text{S}}$$

Here $(U_{1\text{N}})$ is the RMS voltage of one half of the secondary winding and (U_{S}) is the RMS voltage of the full secondary winding.

For the bridge rectifier B2:

$$U_{\text{di}} = \frac{2\sqrt{2}}{\pi} U_{\text{sim}}$$

The ripple frequency is

$$f_{\sigma} = 2f$$

The ideal ripple factor is

$$w_U \approx 0.48$$

Real diode voltage drops

In a bridge rectifier, two diodes conduct at the same time. Therefore, for silicon diodes, the output voltage is roughly reduced by

$$2U_{\text{TO}} \approx 1.4 \sim \text{V}$$

This matters especially for low-voltage supplies.

<tabcaption tab_rectifier_summary|Comparison of simple rectifier circuits>

Circuit	Uses half-waves	Ideal average voltage (U_{di})	Ripple frequency
M1 half-wave	one half-wave	$\frac{\sqrt{2}}{\pi} U_{\text{sim}}$	f
M2 center-tap	both half-waves	$\frac{2\sqrt{2}}{\pi} U_{1\text{N}}$	$2f$
B2 bridge	both half-waves	$\frac{2\sqrt{2}}{\pi} U_{\text{sim}}$	$2f$

Capacitor smoothing

A rectifier output is not constant. A smoothing capacitor stores charge near the voltage maximum and supplies the load between maxima.

Start drawing by clicking here

Fig. ##: Bridge rectifier with smoothing capacitor.

For a bridge rectifier with a sufficiently large smoothing capacitor, the DC voltage is approximately

$$U_{\text{di}} \approx \sqrt{2} U_{\text{sim}}$$

for ideal diodes and small ripple.

With real silicon diodes in a bridge rectifier:

$$U_{\text{di}} \approx \sqrt{2} U_{\text{sim}} - 2U_{\text{TO}} - \frac{\Delta U}{2}$$

Here (ΔU) is the approximate peak-to-peak ripple voltage.

A simple estimate for the smoothing capacitor is

$$C \approx \frac{I_{\text{d}}}{f_{\text{sigma}} \Delta U}$$

with

- (I_{d}) : load current,

- f_{σ} : ripple frequency,
- ΔU : allowed peak-to-peak ripple voltage.

Course approximation with RMS ripple

If U_{σ} is used as the RMS value of the ripple voltage, a practical estimate is

$$C \approx \frac{I_{\text{rd}}}{f_{\sigma} U_{\sigma}}$$

Typical factors:

$$k = 0.25 \text{ \&\text{for one-pulse rectification}}, k = 0.20 \text{ \&\text{for two-pulse rectification}}$$

A larger capacitor reduces ripple, but it also creates short high charging-current pulses through the diodes and transformer. For power supplies, check diode peak current, transformer rating, capacitor ripple current, and inrush current.

Application overview

<tabcaption tab_diode_applications|Typical diode applications in mechatronics and robotics>

Problem	Diode application	Main design question
Status indication	LED with resistor	Which current and resistor value?
Small reference voltage	Z-diode stabilizer	Is I_{Z} inside the allowed range?
Relay or solenoid switch-off	freewheeling diode	Where can the inductor current flow?
Sensor input disturbance	clamp diodes	Is the clamp current limited?
AC to DC conversion	rectifier	M1, M2, or B2?
DC supply with lower ripple	smoothing capacitor	Which ripple voltage is acceptable?

Exercises

Exercise E1.1 Quick check: LED series resistor for a robot status LED

A robot controller provides

$$U_{\text{E}} = 24 \text{ V}$$

A green LED shall operate at

$$U_{\text{F}} = 1.8 \text{ V}, I_{\text{F}} = 10 \text{ mA}$$

- Calculate the required series resistor R_{V} .
- Choose a nearby standard value.
- Calculate the resistor power for your calculated value.

Result

The resistor value is

$$R_V = \frac{U_E - U_F}{I_F} = \frac{24\text{ V} - 1.8\text{ V}}{10\text{ mA}} = 2.22\text{ k}\Omega.$$

A suitable standard value is, for example,

$$R_V = 2.2\text{ k}\Omega.$$

The resistor power is approximately

$$P_R = (U_E - U_F)I_F = 22.2\text{ V} \cdot 10\text{ mA} = 222\text{ mW}.$$

A (0.25 W) resistor is very close to the limit. A (0.5 W) resistor gives more margin.

Exercise E2.1 Quick check: Z-diode stabilizer

A simple Z-diode stabilizer shall generate approximately

$$U_Z = 5.1\text{ V}$$

from

$$U_E = 12\text{ V}.$$

The series resistor is

$$R_V = 470\Omega.$$

The load resistor is

$$R_L = 1.0\text{ k}\Omega.$$

- Calculate (I_V) .
- Calculate (I_L) .
- Calculate (I_Z) .
- Calculate the Z-diode power (P_Z) .

Result

The current through the series resistor is

$$I_{\text{V}} = \frac{U_{\text{E}} - U_{\text{Z}}}{R_{\text{V}}} = \frac{12\text{V} - 5.1\text{V}}{470\Omega} = 14.7\text{mA}$$

The load current is

$$I_{\text{L}} = \frac{U_{\text{Z}}}{R_{\text{L}}} = \frac{5.1\text{V}}{1.0\text{k}\Omega} = 5.1\text{mA}$$

The Z-diode current is

$$I_{\text{Z}} = I_{\text{V}} - I_{\text{L}} = 14.7\text{mA} - 5.1\text{mA} = 9.6\text{mA}$$

The Z-diode power is

$$P_{\text{Z}} = U_{\text{Z}} I_{\text{Z}} = 5.1\text{V} \cdot 9.6\text{mA} = 49\text{mW}$$

This is acceptable only if the datasheet permits this current and power.

Exercise E3.1 Quick check: freewheeling diode energy

A relay coil has

$$L = 80\text{mH}$$

and carries

$$I_0 = 200\text{mA}$$

just before switch-off.

- Calculate the magnetic energy stored in the coil.
- Explain why a freewheeling diode is useful.
- State one disadvantage of a simple freewheeling diode.

Result

The stored magnetic energy is

$$\left[\begin{aligned} W_L &= \frac{1}{2} L I_0^2 = \frac{1}{2} \cdot 80 \text{ mH} \cdot (200 \text{ mA})^2. \end{aligned} \right]$$

Insert SI units:

$$\left[\begin{aligned} W_L &= 0.5 \cdot 0.080 \text{ H} \cdot (0.200 \text{ A})^2 = 1.6 \text{ mJ}. \end{aligned} \right]$$

When the switch opens, this energy must go somewhere. The freewheeling diode provides a safe path for the coil current and limits the overvoltage.

A disadvantage is that the coil current decays more slowly. Therefore, a relay or solenoid may release more slowly.

Exercise E4.1 Quick check: bridge rectifier average voltage

A bridge rectifier B2 is supplied by a sinusoidal AC voltage with

$$\left[\begin{aligned} U_{\text{sim}} &= 12 \text{ V} \end{aligned} \right]$$

at

$$\left[\begin{aligned} f &= 50 \text{ Hz}. \end{aligned} \right]$$

Assume an ohmic load and ideal diodes.

- Calculate the ideal average rectified voltage (U_{di}) .
- State the ripple frequency (f_{sigma}) .
- Compare this with a half-wave rectifier M1 using the same (U_{sim}) .

Result

For the bridge rectifier:

$$\left[\begin{aligned} U_{\text{di},B2} &= \frac{2\sqrt{2}}{\pi} U_{\text{sim}} = \frac{2\sqrt{2}}{\pi} \cdot 12 \text{ V} = 10.8 \text{ V}. \end{aligned} \right]$$

The ripple frequency is

$$\left[\begin{aligned} f_{\text{sigma}} &= 2f = 100 \text{ Hz}. \end{aligned} \right]$$

For the half-wave rectifier:

$$\left[\begin{aligned} U_{\text{di},M1} &= \frac{\sqrt{2}}{\pi} U_{\text{sim}} = \end{aligned} \right]$$

$$\frac{\sqrt{2}}{\pi} \cdot 12 \text{ V} = 5.4 \text{ V}.$$

The bridge rectifier uses both half-waves. Therefore, the average voltage is twice as large and the ripple frequency is doubled.

Exercise E5.1 Longer exercise: small DC supply with bridge rectifier and smoothing capacitor

A 12 V RMS transformer secondary feeds a bridge rectifier with a smoothing capacitor. The mains frequency is

$$f = 50 \text{ Hz}.$$

The load current is

$$I_{\text{d}} = 250 \text{ mA}.$$

The allowed peak-to-peak ripple voltage is

$$\Delta U = 1.0 \text{ V}.$$

Assume silicon diodes with

$$U_{\text{TO}} = 0.7 \text{ V}.$$

- Calculate the peak value of the transformer secondary voltage.
- Estimate the ripple frequency (f_{sigma}) .
- Estimate the required capacitor (C) .
- Estimate the average DC output voltage with ripple and diode drops.
- Explain why the transformer and diodes must tolerate current pulses.

Result

The peak value of the secondary voltage is

$$\hat{U}_{\text{sim}} = \sqrt{2} U_{\text{sim}} = \sqrt{2} \cdot 12 \text{ V} = 17.0 \text{ V}.$$

For a bridge rectifier,

$$f_{\text{sigma}} = 2f = 100 \text{ Hz}.$$

Using

$$\left[\begin{array}{l} C \approx \frac{I_d}{f_{\sigma} \Delta U}, \end{array} \right]$$

we get

$$C \approx \frac{250 \text{ mA}}{100 \text{ Hz} \cdot 1.0 \text{ V}} \\ \approx \frac{0.250 \text{ A}}{100 \text{ s}^{-1} \cdot 1.0 \text{ V}} \approx 2.5 \cdot 10^{-3} \text{ F} = 2500 \mu\text{F}.$$

A nearby practical value would be, for example,

$$C = 2200 \mu\text{F} \quad \text{or} \quad C = 3300 \mu\text{F},$$

depending on the allowed ripple.

In a bridge rectifier, two diodes conduct at the same time, so the diode drop is approximately

$$2U_{\text{TO}} = 1.4 \text{ V}.$$

The average DC output voltage can be estimated as

$$U_d \approx \hat{U}_{\text{sim}} - 2U_{\text{TO}} - \frac{\Delta U}{2} \\ \approx 17.0 \text{ V} - 1.4 \text{ V} - 0.5 \text{ V} \approx 15.1 \text{ V}.$$

The capacitor is recharged only near the peaks of the AC voltage. Therefore the diode current is not a smooth (250 mA) , but occurs in short charging pulses. The diodes, transformer, and capacitor must tolerate these pulse currents.

Common pitfalls

- **Connecting LEDs without current limitation:** The LED current can become destructive.
- **Forgetting resistor power:** In (24 V) control cabinets, LED resistors can dissipate noticeable heat.
- **Using a Z-diode without load-current check:** The Z-current must remain between $(I_{\text{Z,min}})$ and $(I_{\text{Z,max}})$.
- **Using clamp diodes without a series resistor:** The clamp current must be limited.
- **Thinking the freewheeling diode removes energy instantly:** It gives the current a safe path, but turn-off may become slower.
- **Ignoring diode drops in bridge rectifiers:** Two diodes conduct at the same time.
- **Confusing RMS and peak values:** A (12 V) RMS sine has a peak value of about (17 V) .
- **Assuming a smoothing capacitor creates perfect DC:** The output still has ripple and charging-current pulses.
- **Using capacitor formulas without checking ratings:** Check voltage rating, ripple current, polarity, and inrush current.

Embedded resources

Falstad: Half-wave rectifier

Use this simulation to observe how one half-wave is removed by a diode.

Falstad: Bridge rectifier

Use this simulation to compare half-wave and full-wave rectification.

Falstad: Inductive kickback protection

Use this simulation to observe the overvoltage when switching an inductive load, and how a diode limits it.

Falstad: Z-diode voltage reference

Use this simulation to observe how a Z-diode limits the output voltage.
