Fig. 4: Inverting Op-Amp: Photo Diode as current source

$$U_{DD} \approx 10\text{ V}, U_{SS} \approx -10\text{ V}$$

We assume a good illuminated room of 300 lx, illuminated by a white LED. White light is a mixture of many wavelengths across the visible spectrum, roughly 380 to 780 nm. For a typical white LED, the spectrum usually comes from a blue LED chip with a peak around 450 nm, plus a broader phosphor emission that spreads across green, yellow, and red wavelengths. For an easier calculation, we take a mean value of 500 nm which is close to the peak value of the blue LED (in reality a greenish light) and 300 lx for the illumination. The graph in figure 3 shows that the photodiode sensitivity at 500 nm is only 30%. The maximum current (100%) at 300 lx is 30  $\mu\text{A}$ . We can now estimate the current we would expect from the diode at 300 lx:

$$I_1 = 30\ \mu\text{A} * 0.3 = 9\ \mu\text{A}$$

$$I_1 \approx 10\ \mu\text{A}$$

30% of 30  $\mu\text{A}$  is roughly 10  $\mu\text{A}$ .

Complete the arrows in the schematic of the circuit. Calculate  $R_2$  so that  $U_{OUT} = 5\text{ V}$  at 300 lx. Take a resistor from the E6 series that is as close as possible to the calculated value.

$$I_1 \approx$$

$$I_2 \approx$$

$U_{\text{OUT}} \approx$

$U_2 \approx$

$R_2 \approx$

What value would you expect for  $U_D$  and why?

$U_D \approx$

$\{ \dots \}$

$\{ \dots \}$

$\{ \dots \}$

$\{ \dots \}$

$\{ \dots \}$

$\{ \dots \}$

What value would you expect for  $U_D$  at 300 lx when it is not connected to the Op-Amp or any other electronic component (open-circuit voltage) and why?

$\$U_{\text{D}} \approx \$$
